

Economic Growth and Employment

Project Overview

This project examines the relationship between economic growth and employment using the World Bank World Development Indicators dataset from 2010 to 2024. The aim is to understand how economic performance influences employment outcomes across countries and to provide insights that can support informed decision-making.

Key Findings

- Economic growth fluctuated between 2010 and 2024, with a decline around 2020 followed by a strong recovery.
- Unemployment generally decreased over the study period, although temporary increases occurred during periods of economic disruption.
- GDP per capita varied considerably across countries, reflecting differences in economic development.
- Countries with stronger economic growth often experienced lower unemployment rates.
- Labor force participation remained relatively stable across many countries.
- Economic growth alone does not guarantee lower unemployment because other factors also affect job creation.

Conclusion

- Economic growth and employment are closely linked, but growth alone is not enough to solve employment challenges.
- Countries with similar economic growth can experience different employment outcomes.
- Monitoring both economic and labor market indicators supports better planning and policy decisions.
- The findings highlight the value of using data to guide sustainable economic development.

Recommendations

- Promote sustainable economic growth alongside job creation initiatives.
- Invest in education, skills development, and vocational training.
- Support sectors with strong potential to generate employment.
- Monitor economic and employment indicators regularly to evaluate progress.
- Use the findings to guide policy decisions and resource allocation.
